Executive assessment

I audited the current tree at **478aef4f** against the OpenGL and Vulkan implementations and their registered tests. **OpenGL is the more mature and complete implementation of the established rendering behavior; Vulkan has the stronger explicit command/resource model, but is still a port with material compatibility gaps and a less scalable central implementation.** Neither backend is uniformly better.

The migration has meaningful alignment: both support the main viewer workflow and have shared-contract tests for picking, selection, overlays, offscreen queries, and capture. But the repository builds **one backend at a time**, and tests do not provide a direct side-by-side comparison. “Parity” therefore means passing separate backend-specific runs, not demonstrating equivalent outputs for the same scenes.
